Summarizing Known Attacks on Transport Layer Security (TLS) and Datagram TLS (DTLS)

Abstract

Over the last few years, there have been several serious attacks on Transport Layer Security (TLS), including attacks on its most commonly used ciphers and modes of operation. This document summarizes these attacks, with the goal of motivating generic and protocol-specific recommendations on the usage of TLS and Datagram TLS (DTLS).

Status of This Memo

This document is not an Internet Standards Track specification; it is published for informational purposes.

This document is a product of the Internet Engineering Task Force (IETF). It represents the consensus of the IETF community. It has received public review and has been approved for publication by the Internet Engineering Steering Group (IESG). Not all documents approved by the IESG are a candidate for any level of Internet Standard; see Section 2 of RFC 5741.

Information about the current status of this document, any errata, and how to provide feedback on it may be obtained at http://www.rfc-editor.org/info/rfc7457.

1. Introduction

Over the last few years, there have been several major attacks on TLS [RFC5246], including attacks on its most commonly used ciphers and modes of operation. Details are given in Section 2, but a quick summary is that both AES-CBC and RC4, which together make up for most current usage, have been seriously attacked in the context of TLS.

This situation was one of the motivations for the creation of the UTA working group, which was tasked with the creation of generic and protocol-specific recommendations for the use of TLS and DTLS [RFC6347] (unless otherwise noted under Section 3, all of the information provided in this document applies to DTLS).

There is an old saying attributed, ironically enough, to the US National Security Agency (NSA): "Attacks always get better; they never get worse." Unfortunately, that saying is true, so any description of security attacks can only be a snapshot in time. Therefore this document reflects our knowledge as of this writing. It seems likely that new attacks will be discovered in the future.

For a more detailed discussion of the attacks listed here, the interested reader is referred to [Attacks-iSec].

2. Attacks on TLS

This section lists the attacks that motivated the current recommendations in [SECURE-TLS]. This list is not intended to be an extensive survey of the security of TLS.

While there are widely deployed mitigations for some of the attacks listed below, we believe that their root causes necessitate a more systematic solution, which we have attempted to develop in [SECURE-TLS].

When an identifier exists for an attack, we have included its Common Vulnerabilities and Exposures (CVE) ID. CVE [CVE] is an extensive, industry-wide database of software vulnerabilities.

2.1. SSL Stripping

透過修改要求使用TLS的未加密的協定,來移除SSL和TLS的使用

Various attacks attempt to remove the use of Secure Socket Layer / Transport Layer Security (SSL/TLS) altogether by modifying unencrypted protocols that request the use of TLS, specifically modifying HTTP traffic and HTML pages as they pass on the wire. These attacks are known collectively as "SSL Stripping" (a form of the more generic "downgrade attack") and were first introduced by Moxie Marlinspike [SSL-Stripping]. In the context of Web traffic,

如果使用者使用HTTP存取網頁伺服器才會中招。解決之道是使用較安全嚴謹的HSTS

HSTS。
RFC 7457 TLS Attacks February 2015

these attacks are only effective if the client initially accesses a Web server using HTTP. A commonly used mitigation is HTTP Strict Transport Security (HSTS) [RFC6797].

2.2. STARTTLS Command Injection Attack (CVE-2011-0411)

Similarly, there are attacks on the transition between unprotected and TLS-protected traffic. A number of IETF application protocols have used an application-level command, usually STARTTLS, to upgrade a cleartext connection to use TLS. Multiple implementations of STARTTLS had a flaw where an application-layer input buffer retained commands that were pipelined with the STARTTLS command, such that commands received prior to TLS negotiation are executed after TLS negotiation. This problem is resolved by requiring the application-level command input buffer to be empty before negotiating TLS. Note that this flaw lives in the application layer code and does not impact the TLS protocol directly.

STARTTLS and similar mechanisms are vulnerable to downgrade attacks, whereby the attacker simply removes the STARTTLS indication from the (unprotected) request. This cannot be mitigated unless HSTS-like solutions are added.

BEAST的弱點是TLS 1.0的CBC mode 實作

2.3. BEAST (CVE-2011-3389) 使用可預測的IV,使得可以解開部分封包

The BEAST attack [BEAST] uses issues with the TLS 1.0 implementation of Cipher Block Chaining (CBC) (that is, the predictable initialization vector) to decrypt parts of a packet, and specifically to decrypt HTTP cookies when HTTP is run over TLS.

2.4. Padding Oracle Attacks

A consequence of the MAC-then-encrypt design in all current versions of TLS is the existence of padding oracle attacks [Padding-Oracle]. A recent incarnation of these attacks is the Lucky Thirteen attack (CVE-2013-0169) [CBC-Attack], a timing side-channel attack that allows the attacker to decrypt arbitrary ciphertext.

The Lucky Thirteen attack can be mitigated by using authenticated encryption like AES-GCM [RFC5288] or encrypt-then-MAC [RFC7366] instead of the TLS default of MAC-then-encrypt.

An even newer variant of the padding oracle attack, one that does not use timing information, is the POODLE attack (CVE-2014-3566) [POODLE] on SSL 3.0. This attack has no known mitigation.

先MAC再加密的設計使得TLS存在padding oracle attack, Lucky 13 是使用時間消耗旁道攻擊來解開密文。可透過AES-GCM或先加密再MAC的方式來解決。

Sheffer, et al.

Informa

為了與較舊的伺服器溝通,TLS的客戶端通常有降級的設計,若handshake失敗,會從最新的協定慢慢向下調降,最差可能降級到SSL3.0 SSL3.0的CBC加密最嚴重的問題是padding為非決定性的,且未被訊息認證碼(MAC)的範圍所涵蓋,所以解密時無法確認padding的完整性,所以可被利用來作Padding oracle attack

也有攻擊是存在於未受保護和受TLS保護的流量之間,像 是STARTSSL的多數實作,在輸入buffer的機制有一些漏

洞,使得有些在TLS negotiation之前收到的命令會在

negotiation之後執行。解決之道也是使用較安全嚴謹的

RFC 7457

RC4存在許多biases,亦即出現某種特定的 kevstream的機率遠大於其他,可被攻擊者以 Single-byte bias attack或 Double-byte bias attack 攻擊,其中Double-byte bias attack破解整份256 bytes的密文需要13*2/30個加密。

2.5. Attacks on RC4

The RC4 algorithm [RC4] has been used with TLS (and previously, SSL) for many years. RC4 has long been known to have a variety of cryptographic weaknesses, e.g., [RC4-Attack-Pau], [RC4-Attack-Man], and [RC4-Attack-FMS]. Recent cryptanalysis results [RC4-Attack-AlF] exploit biases in the RC4 keystream to recover repeatedly encrypted plaintexts.

These recent results are on the verge of becoming practically exploitable; currently they require 2^26 sessions or 13x2^30 encryptions. As a result, RC4 can no longer be seen as providing a sufficient level of security for TLS sessions. For further details, the reader is referred to [CIPHER-SUITES] and that Land The CRIME is referred to [CIPHER-SUITES] and the content of the reader is referred to [CIPHER-SUITES] and the content of the cont cites.

attack可讓攻擊者解密成功。而TIME 及 2.6. Compression Attacks: CRIME, TIME, and BREACH BREACH attack則是針對HTTP等級的壓

The CRIME attack [CRIME] (CVE-2012-4929) allows an active attacker to decrypt ciphertext (specifically, cookies) when TLS is used with TLSlevel compression.

The TIME attack [TIME] and the later BREACH attack [BREACH] (CVE-2013-3587, though the number has not been officially allocated) both make similar use of HTTP-level compression to decrypt secret data passed in the HTTP response. We note that compression of the HTTP message body is much more prevalent than compression at the TLS level.

The TIME attack can be mitigated by disabling TLS compression. We are not aware of mitigations at the TLS protocol level to the BREACH attack, and so application-level mitigations are needed (see [BREACH]). For example, implementations of HTTP that use Cross-Site Request Forgery (CSRF) tokens will need to randomize them. Even the best practices and recommendations from [SECURE-TLS] are insufficient to thwart this attack.

在TLS上使用RSA憑證時有幾種攻擊法,B法 2.7. Certificate and RSA-Related Attacks 在TLS1.0已被抵擋, K法則在TLS1.1被抵擋

There have been several practical attacks on TLS when used with RSA certificates (the most common use case). These include [Bleichenbacher98] and [Klima03]. While the Bleichenbacher attack has been mitigated in TLS 1.0, the Klima attack, which relies on a version-check oracle, is only mitigated by TLS 1.1.

The use of RSA certificates often involves exploitable timing issues [Brumley03] (CVE-2003-0147), unless the implementation takes care to explicitly eliminate them.

Sheffer, et al.

A recent certificate fuzzing tool [Brubaker2014using] uncovered numerous vulnerabilities in different TLS libraries related to certificate validation.

a recent certificate fuzzing tool [Brubaker2014using] uncovered numerous vulnerabilities in different TLS libraries related to a related t

When TLS is used with most non-Diffie-Hellman cipher suites, it is sufficient to obtain the server's private key in order to decrypt any sessions (past and future) that were initiated with that server. This technique is used, for example, by the popular Wireshark network sniffer to inspect TLS-protected connections.

It is known that stolen (or otherwise obtained) private keys have been used as part of large-scale monitoring [RFC7258] of certain servers.

Such attacks can be mitigated by better protecting the private key, e.g., using OS protections or dedicated hardware. Even more effective is the use of cipher suites that offer "forward secrecy", the property where revealing a secret such as a private key does not expose past or future sessions to a passive attacker.

2.9. Diffie-Hellman Parameters

TLS allows the definition of ephemeral Diffie-Hellman (DH) and Elliptic Curve Diffie-Hellman parameters in its respective key exchange modes. This results in an attack detailed in [Cross-Protocol]. Using predefined DH groups, as proposed in [FFDHE-TLS], would mitigate this attack.

In addition, clients that do not properly verify the received parameters are exposed to man-in-the-middle (MITM) attacks.

Unfortunately, the TLS protocol does not mandate this verification (see [RFC6989] for analogous information for IPsec).

2.10. Renegotiation (CVE-2009-3555)

A major attack on the TLS renegotiation mechanism applies to all current versions of the protocol. The attack and the TLS extension that resolves it are described in [RFC5746].

2.11. Triple Handshake (CVE-2014-1295)

The triple handshake attack [BhargavanDFPS14] enables the attacker to cause two TLS connections to share keying material. This leads to a multitude of attacks, e.g., man-in-the-middle, breaking safe renegotiation, and breaking channel binding via TLS Exporter [RFC5705] or "tls-unique" [RFC5929].

nal

2.9 The attack presents valid explicit elliptic curve Diffie-Hellman parameters signed by a server to a client that incorrectly interprets these parameters as valid plain Diffie-Hellman parameters. Our attack enables an adversary to successfully impersonate a server to a random client after obtaining 2/40 signed elliptic curve keys from the original server

TLS的伺服器使用ECDH參數,可能被客戶端錯誤解讀 為DH參數,導致攻擊者有可能假冒為伺服器與客戶端連 線成功。 2.11 Triple handshake attack讓攻擊者可以讓2個TLS連線使用同一把 Key,使得MITM等攻擊法可行

2.12. Virtual Host Confusion

降級至SSLV3且對伺服器端的session caches不當操作,將使攻擊者可以建立惡意連結到虛擬的主機,而非伺服器端原本想要連結到的主機

A recent article [Delignat14] describes a security issue whereby SSLv3 fallback and improper handling of session caches on the server side can be abused by an attacker to establish a malicious connection to a virtual host other than the one originally intended and approved by the server. This attack is especially serious in performance critical environments where sharing of SSLv3 session caches is very common.

以BOTNETS可以操作DOS

2.13. Denial of Service

Server CPU power has progressed over the years so that TLS can now be turned on by default. However, the risk of malicious clients and coordinated groups of clients ("botnets") mounting denial-of-service attacks is still very real. TLS adds another vector for computational attacks, since a client can easily (with little computational effort) force the server to expend relatively large computational work. It is known that such attacks have in fact been mounted.

2.14. Implementation Issues

Even when the protocol is properly specified, this does not guarantee the security of implementations. In fact, there are very common issues that often plague TLS implementations. In particular, when integrating into higher-level protocols, TLS and its PKI-based authentication are sometimes the source of misunderstandings and implementation "shortcuts". An extensive survey of these issues can be found in [Georgiev2012].

實作的問題 1.可能會忽略驗 證伺服器憑證的 動作 2.可能不會正確 驗證伺服器的身

分。 3.可能無法正確 或完全驗證憑證 的信任鏈結。 4.可能會發生像

4.可能曾發生像 HeartBleed程式 寫錯的簡單錯誤 Implementations might omit validation of the server certificate altogether. For example, this is true of the default implementation of HTTP client libraries in Python 2 (e.g., CVE-2013-2191).

Implementations might not validate the server identity. This validation typically amounts to matching the protocol-level server name with the certificate's Subject Alternative Name field. Note: this same information is often also found in the Common Name part of the Distinguished Name, and some validators incorrectly retrieve it from there instead of from the Subject Alternative Name.

Implementations might validate the certificate chain incorrectly or not at all, or use an incorrect or outdated trust anchor list.

An implementation attack of a different kind, one that exploits a simple coding mistake (bounds check), is the Heartbleed attack (CVE-2014-0160) that affected a wide swath of the Internet when it was discovered in April 2014. 為了可以建立連線,有時候使用者

會接受不合格的伺服器憑證,這有

2.15. Usability

Many TLS endpoints, such as browsers and mail clients, allow the user to explicitly accept an invalid server certificate. This often takes the form of a UI dialog (e.g., "do you accept this server?"), and users have been conditioned to respond in the affirmative in order to allow the connection to take place.

可能導致攻擊。

This user behavior is used by (arguably legitimate) "SSL proxies" that decrypt and re-encrypt the TLS connection in order to enforce local security policy. It is also abused by attackers whose goal is to gain access to the encrypted information.

Mitigation is complex and will probably involve a combination of protocol mechanisms (HSTS, certificate pinning [KEY-PINNING]), and very careful UI design.

3. Applicability to DTLS

DTLS [RFC4347] [RFC6347] is an adaptation of TLS for UDP.

With respect to the attacks described in the current document, DTLS 1.0 is equivalent to TLS 1.1. The only exception is RC4, which is disallowed in DTLS. DTLS 1.2 is equivalent to TLS 1.2.

4. Security Considerations

This document describes protocol attacks in an informational manner and in itself does not have any security implications. Its companion documents, especially [SECURE-TLS], certainly do.
